# 1 Ubuntu App - Windows Subsystem for Linux

# 1.1 WSL2 setup

Installation method of WSL depends on which windows version you are running.

Check your Windows version and build number by pressing

Win + R -> Entering winver

Depending on the version you have, see the below sections.

If you have:

• Windows version 2004 and higher, with build 1904 and higher

Then you can do the **Automatic installation** section.

If that is not the case, then you must at least have:

• Windows version 1903 or higher, with build 18362 or higher

If so, then if running the version

- 1903, the build number must be 18362.1049 or higher
- 1909, the build number must be 18363.1049 or higher

If any of those is true for your system, then you can do the Manual installation section.

# 1.1.1 Automatic installation

A simple command in PowerShell: wsl --install

#### 1.1.2 Manual installation

#### 1.1.2.1 Enable Windows Subsystem for Linux

Open PowerShell as Admin and run:

dism.exe /online /enable-feature /featurename:Microsoft-Windows-Subsystem-Linux /all /norestart

#### 1.1.2.2 Enable Virtual Machine feature

Open PowerShell as Admin and run:

dism.exe /online /enable-feature /featurename:VirtualMachinePlatform /all /norestart

Restart your computer.

# 1.1.2.3 Download the Linux kernel update package

Download the latest package through this link.

## 1.1.2.4 Set WSL 2 as the default version

Every new distribution installed should run with the WSL version set as default.

Open PowerShell and run:

wsl --set-default-version 2

# 1.2 Downloading the Ubuntu distribution

## 1.2.1 Downloading through PowerShell

First we are going to download the Ubuntu distribution with some PowerShell commands.

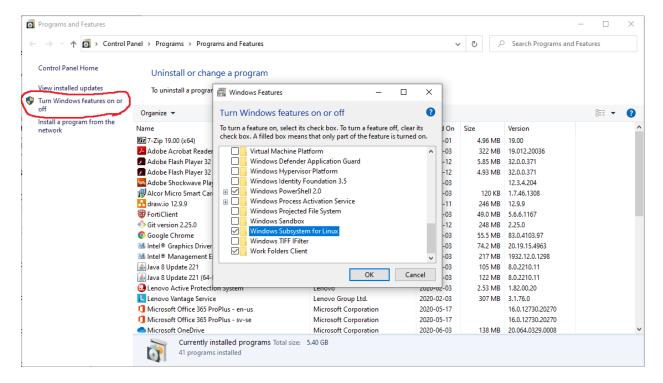

Open PowerShell and go to somewhere in your main drive where you want to install Ubuntu: When unzipping later, a directory named Ubuntu will be created.

cd C:\textbackslash Users\textbackslash <username>\textbackslash

# 1.3 Installation Ubuntu WSL with Visual Studio Code

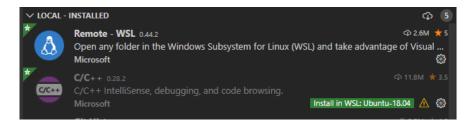

https://code.visualstudio.com/docs/cpp/config-wsl

- 1. Download Ubuntu 18.04 LTS from Windows Store.
- 2. Activate Windows Subsystem for Linux through Programs and Features.

- 3. Restart computer.
- 4. Run Ubuntu 18.04 LTS and let it install. Might have to press enter after a while.
- 5. Create user with password.
- 6. Install gcc and gdb on the Windows Subsystem for Linux (WSL).
  - (a) Run sudo apt update
  - (b) Then sudo apt install build-essential for gcc
  - (c) Then sudo apt install gdb for gdb
- 7. Create a new folder in the WSL where you create a C file helloworld.c. New folder is necessary for Visual Studio Code to realise that there is a C compiler to setup later on as it uses the open file to do the configurations.
- 8. Open up Visual Studio Code.
- 9. Install two extensions in VS code:
  - C/C++ from Microsoft
  - Remote WSL from Microsoft

- 10. Press on the new icon on the left, Remote explorer. Right-click the Ubuntu 18.04 and press Connect to WSL. A new window will appear with some connection to the WSL.
- 11. Press on the extension icon the left in the new window. Press Install in WSL: Ubuntu-18.04 button on the C/C++ extension.

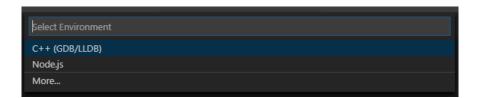

- 12. By now it might prompt that you have to reload the window. Press that button.
- 13. Open up the folder you created the main C file in. File->Open Folder...
- 14. Open up the helloworld.c file in the file explorer.
- 15. Press Terminal->Configure Default Build Task.... In the dropdown list that should appear, choose C/C++: gcc build active file (Not gcc-7). A file tasks.json will be created and opened up.
  - No edits of the tasks.json is required for single file compilation with gcc.
  - Edits are required for multi-file compilation with gcc.

# 1.3.1 Simple single file compilation

- 16. Do not edit the tasks.json
- 17. Build file with Ctrl+Shift+b. Press the + sign at the terminal to open a new terminal. Run the file ./helloworld to test that everything is working.
- 18. Now onto debugging. Press F5 or Run->Start Debugging. In the drop-down list that should appear, choose C++ (GDB/LLDB). A file launch.json will be created and opened up.

- 19. Do not edit the launch.json.
- 20. Down at the Output and Terminal, press the three dots ... and choose Debug Console in which one can run the standard gdb commands.

#### 1.3.2 Multi-file compilation with Makefile

Here is an example of a Makefile I have used. Rembemer to use the -g flag if you want to debug. Also available here https://github.com/robinhellmers/computer\_setup.

This Makefile is based on the following structure.

- Makefile in the main project folder.
- Four sub-folders: bin, src, include, lib
- Executable .out files in bin.
- Main .c files in src.
- Extra .c used as libraries in lib.
- All .h header files in include.

```
CC := gcc
    CFLAGS := -pthread -g
2
    BIN := bin
4
    SRC := src
    INCLUDE := include
6
    LIB := lib
    all: $(BIN)/server.out $(BIN)/client.out
9
10
    $(BIN)/server.out: $(SRC)/server.c $(LIB)/*.c $(INCLUDE)/*.h
11
       $(CC) $(CFLAGS) -I$(INCLUDE) $^ -o $@
12
13
    $(BIN)/client.out: $(SRC)/client.c $(LIB)/*.c $(INCLUDE)/*.h
14
       $(CC) $(CFLAGS) -I$(INCLUDE) $^ -o $@
15
16
17
    clean:
       rm $(BIN)/server.out $(BIN)/client.out
18
19
20
21
    # ${wildcard pattern}
22
    # "wildcard" will list every file that follows the "pattern"
23
    # Lets say we have the files hello.c hello.h goodbye.c goodbye.h
25
    # ${wildcard *.c} will result in: hello.c goodbye.c
```

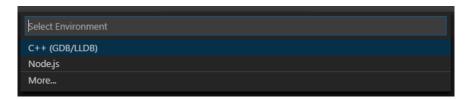

After creating one for the specific project, continue with the **Visual Studio Code** configuration:

- 16. The tasks.json must be edited according to the following.
  - Might have to check if there is some information in the generated tasks.json about the version number.
  - Code also available here: https://github.com/robinhellmers/computer\_setup in the .vscode folder.

- This edit will require a Makefile with an make all command for compiling all the different files together.
- The label "label": "build" can be changed to any other, which will be used in the debugger config file launch.json later on. Same label will appear as a dropdown list later on.

```
{
1
         "version": "2.0.0",
2
         "tasks": [
3
             {
4
                  "type": "shell",
5
                  "label": "build",
6
                  "command": "make all",
                  "group": {
8
                      "kind": "build",
9
                      "isDefault": true
10
                  },
11
                  "problemMatcher": "$gcc"
12
             }
13
        ]
14
    }
```

- 17. Build file with Ctrl+Shift+b. Press the + sign at the terminal to open a new terminal. Run the file ./helloworld to test that everything is working.
- 18. Now onto debugging. Press F5 or Run->Start Debugging. In the drop-down list that should appear, choose C++ (GDB/LLDB). A file launch.json will be created and opened up.

- 19. The launch. json must be edited according to the following.
  - Might have to check if there is some information in the generated tasks.json about the version number.
  - Code also available here: https://github.com/robinhellmers/computer\_setup in the .vscode folder.
  - Set the prelaunch task "preLaunchTask": "build" to the label you set in the tasks.json, in this case to "build". This will do the compilation according to our specification in the tasks.json and thereby compile with the Makefile.
  - Set which program to debug with "program": "\\$\{workspaceFolder\}/bin/\\$\{fileBasenameNoExtension\}.out". This must be adjusted according to the Makefile and where it saves its executable file. Remember to adjust the file ending according to what the Makefile outputs.

```
{
        "version": "0.2.0",
2
        "configurations": [
3
             {
4
                 "name": "gcc - Build and debug active file",
5
                 "type": "cppdbg",
                 "request": "launch",
                 "program": "${workspaceFolder}/bin/${fileBasenameNoExtension}.out",
                 "args": [],
9
                 "stopAtEntry": false,
                 "cwd": "${workspaceFolder}",
11
                 "environment": [],
                 "externalConsole": false,
13
                 "MIMode": "gdb",
                 "setupCommands": [
15
                     {
16
                          "description": "Enable pretty-printing for gdb",
17
                          "text": "-enable-pretty-printing",
18
                          "ignoreFailures": true
19
                     }
20
                 ],
                 "preLaunchTask": "build",
22
                 "miDebuggerPath": "/usr/bin/gdb",
23
                 "sourceFileMap": {
24
                     "/build/glibc-20RdQG": "/usr/src/glibc"
25
26
             }
27
        ]
28
    }
```

Now when debugging and the debugger quits the program, there will always be an error about now able to open a specific file such as /build/glibc-20RdQG or some other letters and numbers after glibc-....

This is not a problem more than that it is annoying. This can be fixed by downloading the files which it wants to open.

- 21. Download glibc compressed file with sudo apt install glibc-source.
- 22. Go to the right directory cd /usr/src/glibc
- 23. Extract the content of the compressed file with sudo tar xf glibc-2.27.tar.xz
- 24. Now add the following, except the most outer curly brackets, to the launch.json file under "configurations": [\{...\}]
  - The letters and numbers after glibc-... must be adjusted to the error message that pops up when the debugger is quitting the program.

#### 1.3.3 Extra

Here is some info about setting up Visual Studio Code to build and debug projects including multiple .c files:

• https://dev.to/talhabalaj/setup-visual-studio-code-for-multi-file-c-projects-1jpi

# 1.3.3.1 Search for multiple words

Some times you might want to find a specific file or line of code with multiple words in it, without having to be in a direct sequence. Use this extension which automates the process of using regex.

#### Search by Alexander:

https://marketplace.visualstudio.com/items?itemName=usernamehw.search

# 1.4 WSL Ubuntu installations

Start with:

sudo apt update

## 1.4.1 Remove files with possibility to restore - trash-cli package

Usually when using the rm command, it is very hard to restore what has been removed. By using this package, a trashbin is being used before removing permanently.

- 1. Install the trash-cli package with sudo apt install trash-cli
- 2. Then set the alias alias rm=trash in your \textapprox /.bashrc file.

The trash-cli package comes with some commands:

- trash Which is like rm but it will be put in a trashbin instead
- trash-list Lists everything in the trashbin
- restore-trash Lists and numbers everything in the trashbin. Asks for an index from the list to
- trash-empty Permanently remove everything in the trashbin.

#### 1.4.2 Terminal bookmark directories

```
Install Apparix (Doc. https://www.micans.org/apparix/) with
sudo apt-get install apparix
```

Run apparix in order for it to set up its folders.

Then write apparix --shell-examples and copy everything except the aliases at the bottom. Paste this in /.bashrc

If just copying from the terminal and pasting into /.bashrc doesn't work, create a file and let the output be written into that instead in order to copy from it.

```
touch text.txt
```

```
apparix --shell-examples > text.txt
```

Then paste it into /.bashrc.

Restart console.

Bookmark current directory with bm bookmarkname and go to the same location with to bookmarkname

## 1.4.3 Compiler gcc & g++

Compiler gcc and g++ installation:

```
sudo apt install build-essential
```

#### 1.4.4 Debugger gdb

```
sudo apt install gdb
```

# 1.4.5 Git

Git installation:

```
sudo apt install git
```

Add credentials that will be asked for later on if not done:

```
git config --global user.email "your@email.com"
```

```
git config --global user.name "your name"
```

Initialize local repository:

git init

# 1.4.5.1 Username and password for remote

Credentials for e.g. Github are stored in ~/.git-credentials as

https://username:password@example.com

Which with **Github** and a token instead of password could be:

https://robinhellmers:generatedtoken@github.com

# 1.4.5.2 Adding Github remote - SSH

Create SSH keys by entering a passphrase connected to the SSH keys, after running:

```
ssh-keygen -f \textapprox /.ssh/id\_ecdsa -t ecdsa -b 521
```

Copy the public key, that is all of the content in id\\_ecdsa.pub. If in WSL Ubuntu, copy the content with:

```
clip.exe < \textapprox /.ssh/id\_ecdsa.pub</pre>
```

Go to Github, then:

Settings → SSH and GPG keys → Add copied public key

In Ubuntu, run the ssh-agent with the command:

```
eval "\$(ssh-agent -s)"
```

Add the SSH keys to the ssh-agent by entering the passphrase after:

```
ssh-add \textapprox /.ssh/id\_ecdsa
```

Now you can clone a repo:

```
git clone git@github.com:<username>/<reponame>.git
```

Say yes to the fingerprint.

# 1.4.5.3 Adding remote - https://

```
git remote add origin <remote-address>
```

Save credentials to .git-credentials:

```
git config credential.helper store
```

Get master from remote origin:

```
git pull origin master
```

In order to not have to specify <remote> and <branch> in git pull <remote> <branch> , but still have to do previous pull first:

```
git branch --set-upstream-to=origin/master master
```

```
git pull
```

In order to pull another branch on the remote, firstly fetch the branches:

#### git fetch

Then see which branches that are fetched e.g.

\* [new branch]\hspace {1.5cm}testing\hspace {0.5cm}-> origin/testing

Checkout that branch. OBS that you don't have a branch created locally, you will only be checking out the remote branch which may change as soon as you git fetch again. This is only in order to copy the content of the remote branch into the local one.

```
git checkout origin/testing
```

Create the local copy of the remote branch and go to it:

```
git checkout -b testing
```

Make sure that the local branch have its upstream to the remote one:

```
git branch --set-upstream-to=origin/testing
```

## 1.4.5.4 View commit history - Short command

In order to have a good git history tree visualization in the terminal, use the .gitconfig from Github. This gives three different commands:

git lg

git 1g2

git 1g3

# 1.4.5.5 Apply .gitignore by removing already committed files - Short command

**NOTE:** This will remove the files from remote repo and thereby remove the files from other computers.

Show the files which currently apply to the .gitignore:

```
git ls-files -ci --exclude-standard
```

Have a command which

- 1. Looks up the .gitignore files
- 2. Removes them locally
- 3. Stages the changes (add): the removed files

Add this line to .gitconfig under [alias] in order to have a short command:

```
apply-gitignore-remove = !git ls-files -ci --exclude-standard -z | xargs -0 git rm --cached
```

Called with:

```
git apply-gitignore-remove
```

Then commit the removed files.

# 1.4.5.6 Ignore already committed file - Short command

```
apply-ignore = git update-index --skip-worktree
```

Called with:

```
git apply-ignore <file>
```

# 1.4.5.7 Multiple users

One might want to have multiple users, e.g. one for work with the work email and a private with private email.

As standard, when doing the commands: git config --global user.name

```
git config --global user.email
```

It created the default user to the \textapprox /.gitconfig by appending

```
[user]
  name = <Your name>
  email = <Your email>
```

You can create another local configuration file \textapprox /<pathToNewGitDirectory>/.gitconfig , with the other user:

```
[user]
  name = <0ther name>
  email = <0ther email>
```

Open up \textapprox /.gitconfig and add [includeIf ...] with your new git configuration file path replaced:

```
[includeIf "gitdir:~/<pathToNewGitDirectory>/"]
path = ~/<pathToNewGitDirectory>/.gitconfig
```

If you are in that directory or any sub-directory specified, your user will be <code>Other name</code> with <code>Other email</code>. Verify this by going to that specified path and type:

```
git config user.name
git config user.email
```

#### 1.4.6 LaTeX

Install the complete version TeX Live:

```
sudo apt install texlive-full
```

## 1.4.6.1 Latex Workshop

```
"tools": [
6
                  "latexmk"
7
                  ]
             },
9
10
                  "name": "pdflatex - bibtex - pdflatex x2",
11
                  "tools": [
12
                  "pdflatex",
13
                  "bibtex",
                  "pdflatex",
15
                  "pdflatex"
16
                  ]
17
             }
18
         ],
19
         "latex-workshop.latex.tools": [
20
21
                  "name": "latexmk",
22
                  "command": "latexmk",
23
                  "args": [
24
                  "-synctex=1",
                  "-interaction=nonstopmode",
26
                  "-file-line-error",
                  "-pdf",
28
                  "-shell-escape",
                  "-outdir=%0UTDIR%",
30
                  " %DOC%"
31
                  ],
32
                  "env": {}
33
             },
34
             {
35
                  "name": "pdflatex",
36
                  "command": "pdflatex",
37
                  "args": [
38
                  "-synctex=1",
39
                  "-interaction=nonstopmode",
40
                  "-file-line-error",
41
                  " %DOC%"
42
                  ],
43
                  "env": {}
44
             },
45
                  "name": "bibtex",
47
                  "command": "bibtex",
48
                  "args": [
49
                  "%DOCFILE%"
50
                  ],s
51
                  "env": {}
52
             }
53
54
```

#### 1.4.6.2 Minted - Code

In order to use the minted package for displaying code one must install Pygments for Python.

If using Ubuntu 18.04:

```
sudo apt install python-pygments
```

If using Ubuntu 20.04:

```
sudo apt install python3-pygments
```

Also, one must use the shell-escape flag with the latexmk (standard compilation) command in order to compile with minted.

In Visual Studio Code, press Ctrl + Shift + P in order to search for commands. Search and execute Preferences: Open settings (JSON) in order to open up the settings.json file with the compilation recipe. Add "-shell-escape" to the arguments.

If the file is empty, use the settings.json from Github.

```
{
         "name": "latexmk",
2
         "command": "latexmk",
3
         "args": [
             "-shell-escape",
5
             "-synctex=1",
             "-interaction=nonstopmode",
             "-file-line-error",
8
             "-pdf",
9
             "-outdir=%OUTDIR%",
10
             "%DOC%"
        ],
12
         "env": {}
13
14
```

If there there is an error message similar to Undefined control sequence. \textbackslash PYG \#1\#2->\textbackslash add the argument cache=false when loading the minted package.

\textbackslash usepackage[cache=false]\{minted\}

# 1.4.6.3 Visually continue row on new line

Text visually continue on new line if row is too long, edit the shortcut key for View: Toggle Word Wrap in File->Preferences->Keyboard Shortcuts

#### 1.4.6.4 Glossaries

In order for glossaries to work, one must call makeglossaries.

```
\mathrm{E.g.} pdflatex <file>.tex 
ightarrow makeglossaries <file> 
ightarrow pdflatex <file>.text
```

But with latex-workshop in VSCode, the standard compilation tool is latexmk which does a series of calls with e.g. pdflatex, bibtex, etc.

In order to make latexmk include a call of makeglossaries, create the file ~/.latexmkrc from Github.

# 1.5 Ubuntu terminal colors

## 1.5.1 Everything step-by-step

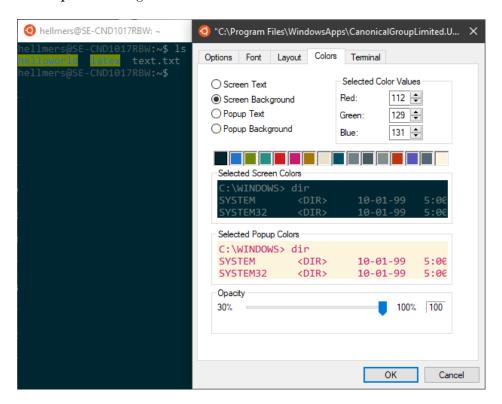

A top-down list of everything in section 1.5.2, 1.5.3 and 1.5.4. Concentrating on what to actually do, without much explanation.

- a) Get ColorTool from Microsoft in order to set a theme.
  - 1. Go to https://github.com/microsoft/terminal/tree/master/src/tools/ColorTool
  - 2. Click the link under the title **Installing** in README.md in order to see the latest release. E.g. https://github.com/microsoft/terminal/releases/tag/1904.29002
  - 3. Download the ColorTool zip file.
- b) Activate a theme with ColorTool.
  - 1. Open Command Prompt in Windows.
  - 2. In CMD look at the PATH variable with PATH or echo \%PATH\%
  - 3. Copy one of the locations shown to store the ColorTool and color scheme.

    E.g. C:\textbackslash Users\textbackslash Robin.Hellmers\textbackslash AppData\textbackslash Locations
  - 4. Unzip the files in that location.
  - 5. Go to the very same directory in CMD with E.g. cd C:\textbackslash Users\textbackslash Robin.Hellmers\textbackslash AppData\textbackslash
  - 6. In the CMD, run ColorTool -b solarized\\_dark.itermcolors.
  - 7. Restart the Ubuntu terminal.
- c) Fix directory highlight inconsistency (Different permissions for Windows and Ubuntu).
  - 1. In the Ubuntu terminal, run dircolors -p > ~/.dircolors
  - 2. Find DIR, STICKY\\_OTHER\\_VARIABLE, STICKY and write their corresponding values in the comments in case one want to revert the upcoming changes.
  - 3. Find OTHER\\_WRITABLE and copy the variable value e.g. 34;42.
  - 4. Replace the values of DIR, STICKY\\_OTHER\\_VARIABLE, STICKY with the copied value.
  - 5. Restart the Ubuntu terminal.
- d) Set specific colors with the properties tool
  - BE CAREFUL, weird tool
  - In order to revert back

    - b) Open up **Properties** and the **Colors** tab. Click OK to recreate the registry which you removed.
  - 1. Open the Ubuntu terminal.

2. Right-click on the top bar which says e.g. **Ubuntu 18.04 LTS** to the right of the icon logo. Press **Properties** and go to the **Color** tab.

- 3. Click between **Screen Background** and **Screen Text** in order to see which colors are highlighted and chosen as standard for each. Remember which is highlighted for which (main colors).
  - In order to see the RGB values, you must click on the highlighted color. But beware that the color which you select must be the highlighted one for that specific category e.g. **Screen Background** or else you will change it.

4. Choose **Screen Background** and select the 3rd color (green).

5. Replace the RGB colors to the same as the figure below.

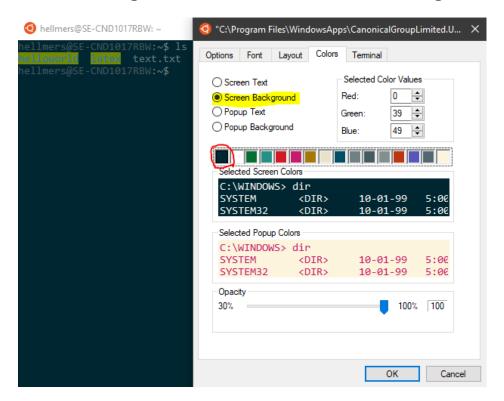

6. Choose **Screen Text** and select the 2nd color (blue).

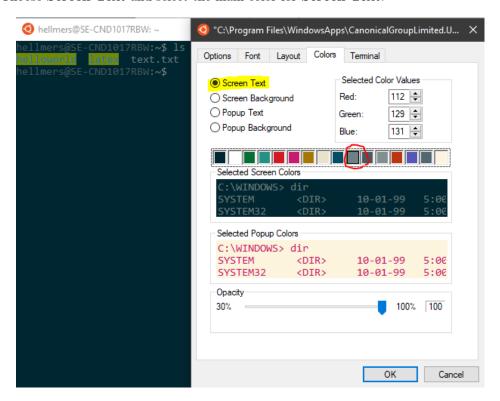

7. Replace the RGB colors to the same as the figure below.

8. Choose Screen Background and select the main color for Screen Background.

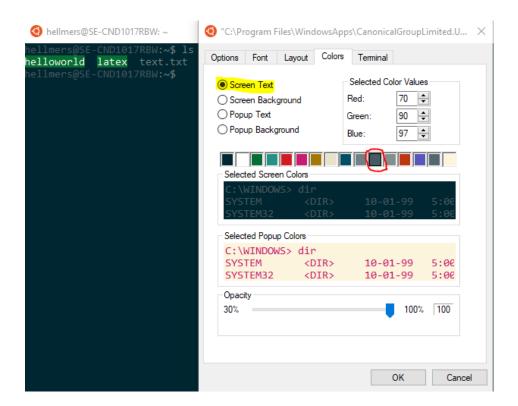

9. Choose Screen Text and select the main color for Screen Text.

10. Press OK to save the changes.

```
ellmers@SE-CND1017RBW:~
hellmers@SE-CND1017RBW:~$ ls
helloworld latex text.txt
hellmers@SE-CND1017RBW:~$
```

- 11. Open up **Properties** and the **Colors** tab again.
- 12. Choose **Screen Text** and select the 11th color (grey).

13. Replace the RGB colors to the same as the figure below.

14. Select the main color for **Screen Text**.

15. Replace the RGB colors to the same as the figure below.

16. Click OK to save the changes.

```
ellmers@SE-CND1017RBW:~
hellmers@SE-CND1017RBW:~$ ls
helloworld latex text.txt
hellmers@SE-CND1017RBW:~$
```

- e) Change vimdiff colors
  - 1. Create the directory \textapprox /.vim/colors/.
  - 2. Create the file \textapprox /.vim/color/mycolorscheme.vim
  - 3. Paste this into the file (see Github):

```
highlight DiffAdd cterm=bold ctermfg=15 ctermbg=22 gui=none guifg=bg guibg=Red highlight DiffChange cterm=bold ctermfg=15 ctermbg=88 gui=none guifg=bg guibg=Red highlight DiffChange cterm=bold ctermfg=15 ctermbg=17 gui=none guifg=bg guibg=Red highlight DiffText cterm=bold ctermfg=15 ctermbg=130 gui=none guifg=bg guibg=Red
```

- 4. Create the file \textapprox /.vimrc
- 5. Paste this into the file (see Github):

```
if &diff
colorscheme mycolorscheme
endif
```

6. Now the custom color scheme should be applied every time you open vimdiff.

#### 1.5.2 Basic colors with Colortool

Colors in the Ubuntu App can be bad. Microsoft have released ColorTool to fix this. See the link below:

https://github.com/microsoft/terminal/tree/master/src/tools/ColorTool

Further down, README.md should have a title Installing with a link to the latest ColorTool release, with a built .exe file and a schemes directory. Here is the current one upon writing this:

https://github.com/microsoft/terminal/releases/tag/1904.29002

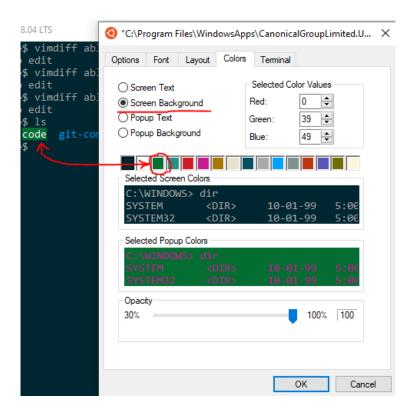

I currently use the solarized\_dark.itermcolors scheme with some additional manual adjustment in properties, described in section 1.5.3.

- 1. Download the zip file.
- 2. Open Command Prompt in Windows.
- 3. Write PATH or echo \%PATH\% if that doesn't work, to see the different paths.
- 4. Find a suitable location, such as C:\textbackslash Users\textbackslash Robin.Hellmers\textbackslash AppDat to unzip the files. Unzip them.
- 5. Open Command prompt at the very same directory.
- 6. Check the schemes directory for the names of the different schemes e.g. campbell.ini, OneHalfDark.itermcolors,
- 7. In the cmd, run ColorTool -b \{scheme\} e.g. ColorTool -b solarized\\_dark.itermcolors.
- 8. Restart the Ubuntu app and the color scheme is applied.

#### 1.5.3 Specific colors with properties tool

- 1. Open up the Ubuntu app.
- 2. Right-click on the top bar which says **Ubuntu 18.04 LTS** besides the icon logo. Press **Properties**. Go to the **Color** tab.
- 3. It is a weird color tool. When pressing **Screen Text** and **Screen Background**, observe which colors that are highlighted and note it down. These must be selected just before pressing **OK** later on.
  - These two selections are the main colors. The main background and main text. The selected ones, when pressing **OK** becomes the main colors.
  - One have to be careful of changing the colors as it is hard to reset them later on.
- 4. Lets say the you want to change this green highlight (Screen Background). Press **Screen Background** and observe which color that is highlighted and thereby is the main color. Press the same green color as the one you want to change.

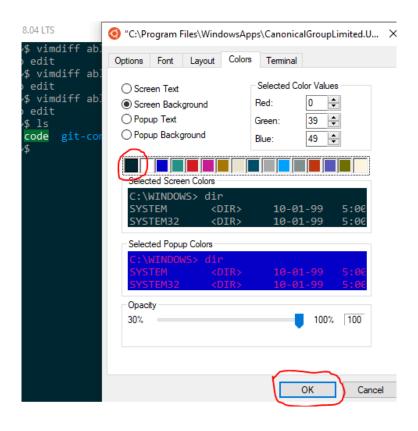

5. As the color you want to change is highlighted, change the RGB values to what you want to have instead.

6. Press the previously highlighted (main color) and then press **OK**. Then the color have been changed.

hellmers:~\$ ls abl bla <mark>code</mark> git-completion.bash hellmers:~\$

One might want to change a text color for a specific highlight color. This is done by

- 1. Press Screen Background
- 2. Note which color that is marked. That is the main background color.
- 3. Select the highlight color which you want to change the text color for
- 4. Press Screen Text
- 5. Note which color that is marked. That is the main text color.
- 6. Select the text color you want for that highlight color
- 7. Press Screen Background
- 8. Select the noted background color from step 2.
  - ullet This will keep your main background color as the last selected one when pressing  ${\bf O}{\bf K}$  is the one becoming the main.
- 9. Press Screen Text
- 10. Select the noted text color from step 5.
  - This will keep your main text color as the last selected one when pressing **OK** is the one becoming the main.

Here are some of my colors:

#### 1.5.4 Fix directory highlight inconsistency

Depending if you have created the directories within Ubuntu WSL directly with mkdir or pulled a directory, which were made within Windows, through some version control system; the background or highlight coloring of these directory may vary.

Probably will the directories made within Windows have another highlight color and this is because these by default have other reading and writing permissions than the ones made within Ubuntu.

Windows made directories probably have <code>o+w</code> permission. Enabling others than the user to write to it. This is called "writable by other". The Ubuntu made ones are probably sticky, which means that they have their sticky bit enabled.

We do not want to change permissions in order to change the colors of the directories. Instead we change the colors of the different permissions and make the two have the same colors.

In .bashrc there are some lines trying to access the file ~/.dircolors. But if you check, there are no such file.

We create it with this command:

```
dircolors -p > \textapprox /.dircolors
```

Then in order to change the colors of the different permissions; find the corresponding keyword and change the numbers. The background color used for the Windows made directories with "writable by other" permission, is set by the variable <code>OTHER\\_WRITABLE</code>. E.g.

```
OTHER\_WRITABLE 34;42 \# dir that is other-writable (o+w) and not sticky
```

It is probably sufficient to copy this value into the DIR variable. From this

```
DIR 01;34 \# directory
```

to this

```
DIR 34;42 \# directory
```

and it is a good idea to save the default value in a comment

```
DIR 34;42 \# default 01;34 directory
```

It could also be a good idea to copy the value into the variables STICKY\\_OTHER\\_VARIABLE and STICKY . Restart the terminal.

#### 1.5.5 Vimdiff colors

The default colors of vimdiff can be really bad because of the translation from 16-bit colors to 256-bit colors.

Code can be found here:

https://github.com/robinhellmers/computer\_setup/

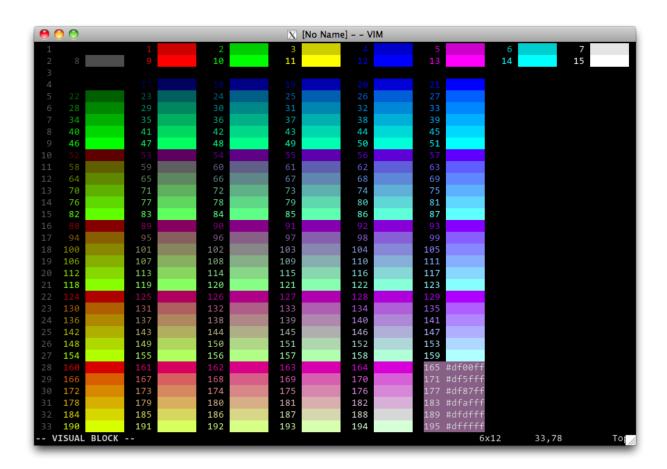

This can be fixed to something like this instead:

```
haluli
hallo
hallo hallo
hallo hallo
sd
new line
```

- 1. Create the \textapprox /.vim/colors/ directory.
- 2. Create a file mycolorscheme.vim in \textapprox /.vim/color/.
- 3. Paste this into the file (see Github):

```
highlight DiffAdd cterm=bold ctermfg=15 ctermbg=22 gui=none guifg=bg guibg=Red
highlight DiffDelete cterm=bold ctermfg=15 ctermbg=88 gui=none guifg=bg guibg=Red
highlight DiffChange cterm=bold ctermfg=15 ctermbg=17 gui=none guifg=bg guibg=Red
highlight DiffText cterm=bold ctermfg=15 ctermbg=130 gui=none guifg=bg guibg=Red
```

- ctermfg = foreground/text color
- ctermbg = background/highlight color
- Values given by xterm256 color table. This table might not correspond exactly to what you see on screen. Thereby it is better to print them out manually.

(a) Create a file color\\_demo.vim anywhere.

(b) Paste this into the file (see Github):

```
let num = 255
while num >= 0
    exec 'hi col_'.num.' ctermbg='.num.' ctermfg=white'
    exec 'syn match col_'.num.' "ctermbg='.num.':...." containedIn=ALL'
    call append(0, 'ctermbg='.num.':....')
    let num = num - 1
endwhile
```

- (c) Open it up with vim color\\_demo.vim and then use the command :so color\\_demo.vim.
- (d) This shows the background colors with corresponding values. Use **Page Up** and **Page down** to go through it.

- 4. You can continuously edit \textapprox /.vim/colors/mycolorscheme.vim and see the updates of the colors while still in vimdiff by using the command :colo mycolorscheme.
- 5. Now we are going to set this scheme permanently for vimdiff. Create a file in your home directory \textapprox /.vimrc.

6. Paste this into the file (see Github):

```
if &diff
colorscheme mycolorscheme
endif
```

7. Now the custom color scheme should be applied every time you open vimdiff.

# 1.6 WSL Ubuntu Customization

# 1.6.1 Terminal shorten name & path, add git indication

Only this link is needed. The rest below this is the same, Github is used to easily copy the code. Github with .bashrc code and git-completion.bash forked from official Git source code:

https://github.com/robinhellmers/computer\_setup

Use sudo chmod +x \textapprox /.git-completion.bash in order to give permission to the user to run it. Thereby it can run it through ./bashrc

Instructions for git fetched from here:

https://git-scm.com/book/id/v2/Appendix-A%3A-Git-in-Other-Environments-Git-in-Bash

Git source code git-completion.bash. Copy the content of the file from official git and add it to your home folder as git-completion.bash:

https://github.com/git/git/blob/master/contrib/completion/git-completion.bash

Add this above the code that is going to be replaced:

```
export PROMPT_DIRTRIM=3
PS1_custom='${debian_chroot:+($debian_chroot)}\[\033[01;32m\]\u\[\033[00m\]:
\[\033[01;34m\]\w\[\033[00m\]\$'
```

## Replace the similar code with this:

## Add this below the code that is going to be replaced:

```
export GIT_PS1_SHOWCOLORHINTS=true
export GIT_PS1_SHOWDIRTYSTATE=true
export GIT_PS1_SHOWUNTRACKEDFILES=true
export GIT_PS1_SHOWUPSTREAM="auto"

# PROMPT_COMMAND='__git_ps1 "\u0\h:\w" "\\$ "'
# use existing PS1 settings
PROMPT_COMMAND=$(sed -r 's|^(.+)(\\$\s*)$|__git_ps1 "\1" "\2"|' <<< $PS1)</pre>
```

#### Here is all of the above:

```
export PROMPT_DIRTRIM=3
     PS1\_custom='\$\{debian\_chroot:+(\$debian\_chroot)\} [\033[01;32m] \u\[\033[00m]:\] 
2
    [\033[01;34m\]\w\[\033[00m\]\'
3
5
    if [ "$color_prompt" = yes ]; then
        PS1=$PS1_custom
    else
        PS1='${debian_chroot:+($debian_chroot)}\u@\h:\w\$'
9
    fi
10
    unset color_prompt force_color_prompt
11
12
13
    export GIT_PS1_SHOWCOLORHINTS=true
14
    export GIT_PS1_SHOWDIRTYSTATE=true
15
    export GIT_PS1_SHOWUNTRACKEDFILES=true
16
    export GIT_PS1_SHOWUPSTREAM="auto"
17
    \# PROMPT_COMMAND='__qit_ps1 "\u@\h:\w" "\\\$ "'
18
    # use existing PS1 settings
19
    \label{eq:prompt_command} $$ PROMPT_COMMAND= (sed -r 's|^(.+)(\\\s*) = git_ps1 "\1" "\2"|' <<< $PS1) $$
20
```

If something says that permission is denied to the file path\\_to\\_file/git-completion.bash . Then run chmod +x path\\_to\\_file/git-completion.bash and restart the Ubuntu app.

## 1.6.1.1 Step-by-step

- 1. Download git-completion.bash from this Github and copy the code.
- 2. Create a new file \textapprox /.git-completion.bash (with dot to make it hidden) and paste the code into it.
- 3. Use sudo chmod +x \textapprox /.git-completion.bash in order to give permission to the user to run it through .bashrc.
- 4. Download bashrc\_shorten\_path\_git from this Github and copy the code.
- 5. Open up \textapprox /.bashrc and find the code similar to this and replace it with the copied code.

```
if [ "$color_prompt" = yes ]; then
    PS1='${debian_chroot:+($debian_chroot)}\[\033[01;32m\]\u@\h\[\033[00m\]: ...'
else
    PS1='${debian_chroot:+($debian_chroot)}\u@\h:\w\$ '
fi
unset color_prompt force_color_prompt
```

# 2 Virtual Machine Setup

# 2.1 Installation VirtualBox & Ubuntu 18.04

- 1. Download .iso file of Ubuntu 18.04.
- 2. Download and install VirtualBox.
- 3. Create new virtual machine.
  - (a) Version: Ubuntu (64-bit); If not showing 64-bit, enable Virtual Machine in BIOS of host machine.
  - (b) Next. Memory 4-5 GB if total 8 GB.
  - (c) Next. Select Create a virtual hard disk now.
  - (d) Create. Select VDI.
  - (e) Next. Select Dynamical.
  - (f) Next. 20-40 GB size. More towards 40 GB.
  - (g) Create. Wait on creating storage. Done.
- 4. Settings of virtual machine.
  - $\rightarrow$  System  $\rightarrow$  Motherboard; Memory still 4-5 GB.
  - $\bullet$   $\to$  System  $\to$  Motherboard; Enable I/O APIC
  - $\rightarrow$  System  $\rightarrow$  Processor; 2 CPUs if total of 4 CPUs.
  - $\rightarrow$  Display  $\rightarrow$  Screen; Max graphics memory.
- 5. Start virtual machine. Should ask for start-up disk where you add the .iso file in Optical Disk Selector. If not showing up follow following:
  - (a) Go to settings  $\rightarrow$  Storage.
  - (b) Mark sub-group to Controller: IDE.
  - (c) Under Attributes  $\rightarrow$  Optical Drive; Press the circular button to the right.
  - (d) Select Choose/Create a Virtual Optical Disk...
  - (e) Add the .iso file.
  - (f) Start virtual machine.
- 6. Choose to install Ubuntu.
- 7. Follow the steps and in one of the steps choose Erase disk and install Ubuntu. As this is a virtual machine, nothing will be erased on the host computer.

# 2.2 VirtualBox Extra Setup

#### 2.2.1 Full-screen

- 1. Start virtual machine.
- 2. Press Devices drop down list in the virtual box window. That is, not inside the virtual machine itself.
- 3. Press Insert Guest Additions CD image...
- 4. A popup in the virtual machine should show: ... contains software intended to be automatically started. Would you like to run it? and choose Run.
- 5. Resize the window a little and it will be full-screen.

# 2.2.2 Shared clipboard

- 1. In virtual box settings go to General->Advanced and select Bidirectional for Shared Clipboard:
- 2. Start virtual machine and see if it is working. If not, continue
- 3. Press Devices drop down list in the virtual box window. That is, not inside the virtual machine itself. Press Insert Guest Additions CD image...
- 4. If an error occurs do the following and then redo it
  - Unmount VBoxGuestAdditons by Devices->Optical Drives->Remove disk from virtual drive.
- 5. Reboot the virtual machine.
- 6. If it is not working, continue
- 7. Download and install Extension pack from virtual box.
- 8. Reboot the virtual machine.
- 9. If it is not working, try unmount and mount guest additions again.

# 2.2.3 Network setup for server and client IPv4 addresses

When starting virtual machine: Ctrl + Alt + T for terminal.

Write: ip addr show, check wether ip-address is something like 192.11.1.24 and not 10.0.1.1.

If something with 10. (...), then it is a local IPv4 address and not one from the DHCP of the router.

Solution: Turn off virtual machine. Go to  $\rightarrow$  Settings  $\rightarrow$  Network and in Attached to: choose Bridged Adapter instead of probably NAT.

Start virtual machine and check if IPv4 address have changed to something like 192.(...).

If you open up a web-browser and don't get a connection, more settings have to be changed.

This probably depends on the virtual machine giving the router one MAC address and the host computer giving another.

Solution: Turn off virtual machine. Go to  $\rightarrow$  Settings  $\rightarrow$  Network and expand Advanced. Remove the MAC address. Then go to the host computer in Windows 10 and open CMD. Write: ipconfig /all and look for the MAC address of the host machine, probably named something like

Input this instead of the old removed MAC address and save. This probably makes you unable to use internet on the host machine instead which one will have to sacrifice.

# 2.3 VM Ubuntu installations

Everything in section 1.4 should be done.

# 2.3.1 Visual Studio Code

Install VS Code:

sudo snap install --classic code

# 3 Python

# 3.1 Python3 in Visual Studio Code

 $\verb|https://stackoverflow.com/questions/50993566/vscode-there-is-no-pip-installer-available-in-the-selected and the selected and the selected$ 

# 4 Extra

# 4.1 Vim Settings

Create \textapprox /.vimrc.

In order to permanently have numbering in vim/vi/vimdiff, add :set number into .vimrc.

# 4.2 Change keyboard layout - MicroSoft Keyboard Layout Creator (MSKLC)

Download MicroSoft Keyboard Layout Creator (MSKLC): https://www.microsoft.com/en-us/download/details.aspx?id=102134

Extract the files and run the installation. If the installation says that .NET Framework has to be installed, then follow the instructions below.

- 1. Press Windows + R.Run appwiz.cpl.
- 2. Click 'Turn Windows features on or off'.
- 3. Enable .NET Framework 3.5 (includes .NET 2.0 and 3.0).
- 4. Follow the on-screen instructions and let Windows install the necessary files.
- 5. Now try to install MSKLC again.

Now run Microsoft Keyboard Layout Creator ....

- 1. Click File → Load Existing Keyboard and pick the keyboard which the computer have e.g. Swedish
- 2. Now save a backup by clicking File → Save Source File As....
- 3. Now change the name of the current keyboard to avoid saving on the backup after doing the changes. Click Project → Properties and change the name etc. as before but to another name such as Custom.
- 4. Now, do the changes to the keyboard layout as you which.
  - { mapped to AltGr + A
  - [mapped to AltGr + S
  - | mapped to AltGr + D
  - } mapped to AltGr + F
  - \ mapped to AltGr + G
- 5. Run the validation by clicking  $Project \rightarrow Validate Layout$  and watch for errors. The warnings can usually be ignored.
- 6. Test write with the layout by clicking Project → Test Keyboard Layout.

- 7. Create the necessary files for the final keyboard layout by clicking Project → Build DLL and Setup Package. When asked about opening the directory where the files were created, click Yes. Usually created in ...\Documents.
- 8. Run the setup file and restart the computer.

# 4.3 Windows code compare program - Meld

Comparing and inserting code. Great when someone sends you a changed file and might want to integrate it into yours. https://meldmerge.org/

# Appendix

# Some appendix section

Some appendix text to the code
